0 Appetizer: Using probability to cover a geometric set

A point $x \in \mathbb{R}^n$ is a **convex combination** of points $x_1, ..., x_m \in \mathbb{R}^n$ if

$$x = \sum_{i=1}^{m} \lambda_i x_i$$
 with each $\lambda_i \ge 0$ and $\sum_{i=1}^{m} \lambda_i = 1$.

The **convex hull** of $T \subseteq \mathbb{R}^n$, conv(T), is the set of all convex combinations of T.

Theorem 0.0.1 (Catheodory's Theorem). Let $x \in \text{conv}(T)$. There exists $k \leq n+1$ points $x_1, ..., x_k \in T$ such that x is a convex combination of $x_1, ..., x_k$.

The result says we can obtain any point in the convex hull of T using at most a dimension-dependent number of points. Let the **diameter** of a set T be defined as $diam(T) = \sup\{\|x - y\|_2 : x, y \in T\}$.

Theorem 0.0.2 (Approximate Catheodory's Theorem). Let diam(T) = 1. Let $x \in \text{conv}(T)$. For any k, there exists k points $x_1, ..., x_k \in T$ such that

$$\left\| x - \frac{1}{k} \sum_{j=1}^{k} x_j \right\|_2 \le \frac{1}{\sqrt{k}}$$

Proof. Suppose |T| = m. WLOG we can assume T is bounded by 1 in $\|\cdot\|_2$. We write $x = \sum_{i=1}^m \lambda_i x_i$, and interpret λ_i as probabilities. We define the random variable

$$X = x_i$$
 with probability λ_i

for i=1,...,m. We can verify that $\mathbb{E}X=\sum_{i=1}^m\lambda_ix_i=x$. Taking $X_1,...,X_k\stackrel{\mathrm{iid}}{\sim}X$. It remains to analyse the quantity $\mathbb{E}\|x-\frac{1}{k}\sum_{j=1}^kX_j\|_2^2$.

$$\mathbb{E} \left\| x - \frac{1}{k} \sum_{j=1}^{k} X_j \right\|_2^2 \le \frac{1}{k^2} \mathbb{E} \left\| \sum_{j=1}^{k} X_j - x \right\|_2^2$$

$$= \frac{1}{k^2} \sum_{j=1}^{k} \mathbb{E} \left\| X_j - x \right\|_2^2 \qquad \text{(by Exercise 0.0.3 (a))}$$

$$= \frac{1}{k} \mathbb{E} \| X - x \|_2^2$$

Applying the result of Exercise 0.0.3 (b), we obtain

$$\mathbb{E}||X - x||_2^2 = \mathbb{E}||X||_2^2 - ||\mathbb{E}X||_2^2 \le \mathbb{E}||X||_2^2 \le 1$$

Plugging this in above, we obtain the desired bound in expectation, hence there must exist a realization of the X_j , $x_1, ..., x_k$, such that the bound holds.

Exercise 0.0.3. Check the following identities for random vectors.

(a) Let $X_1, ..., X_k$ be independent, mean zero random vectors in \mathbb{R}^n . Show that

$$\mathbb{E} \left\| \sum_{j=1}^{k} X_j \right\|_{2}^{2} = \mathbb{E} \sum_{j=1}^{k} \|X_j\|_{2}^{2}$$

Answer.

$$\mathbb{E} \left\| \sum_{j=1}^{k} X_j \right\|_2^2 = \sum_{i=1}^{n} \mathbb{E} \left(\sum_{j=1}^{m} X_j^{(i)} \right)^2 = \sum_{i=1}^{n} \operatorname{Var} \left(\sum_{j=1}^{m} X_j^{(i)} \right)$$
 (by mean zero)
$$= \sum_{i=1}^{n} \sum_{j=1}^{m} \operatorname{Var} \left(X_j^{(i)} \right)$$
 (by independence)
$$= \sum_{i=1}^{n} \sum_{j=1}^{m} \mathbb{E} \left(X_j^{(i)} \right)^2$$
 (by mean zero)
$$= \mathbb{E} \sum_{j=1}^{m} \|X_j\|_2^2$$

Among other things, this result implies that the expected squared distance of a random walk (starting from the origin) is equal to sum of the expected squared distances of each step.

(b) Let X be a random vector in \mathbb{R}^n . Show that

$$\mathbb{E}||X - \mathbb{E}X||_2^2 = \mathbb{E}||X||_2^2 - ||\mathbb{E}X||_2^2$$

Answer.

$$\mathbb{E}||X - \mathbb{E}X||_{2}^{2} = \mathbb{E}\sum_{i=1}^{n} \left(X^{(i)} - (\mathbb{E}X)^{(i)}\right)^{2} = \sum_{i=1}^{n} \operatorname{Var}(X^{(i)}) = \sum_{i=1}^{n} \mathbb{E}\left(X^{(i)}\right)^{2} - \left(\mathbb{E}X^{(i)}\right)^{2} = \mathbb{E}||X||_{2}^{2} - ||\mathbb{E}X||_{2}^{2}$$

Corollary 0.0.4 (Covering polytopes by balls). Let $P \subseteq \mathbb{R}^n$ be a polytope with diam(P) = 1. Let m be the number of vertices of P. Let $\varepsilon > 0$. We can cover P with m^k balls of radius ε for $k \ge \lceil 1/\varepsilon^2 \rceil$.

Proof. Take T to be the vertex set of P. |T| = m. Note that for any $x \in P$, $x \in \text{conv}(T)$. By Theorem 0.0.2, taking $k \ge \lceil 1/\varepsilon^2 \rceil$, we can find $x_1, ..., x_k \in T$ such that

$$\left\| x - \frac{1}{k} \sum_{j=1}^{k} x_j \right\| \le \frac{1}{\sqrt{k}} \le \varepsilon$$

The number of ball centres obtained from selecting a set of k points out of m with repetition is bounded by m^k (possibly repeating orders). Hence we have an ε -cover sufficient to cover P.

Exercise 0.0.5 (Bionomial coefficient inequality). Show that for $1 \le r \le n$

$$\left(\frac{n}{r}\right)^r \le \binom{n}{r} \le \sum_{k=0}^r \binom{n}{k} \le \left(\frac{en}{r}\right)^r$$

Answer. For the first inequality, consider

$$\frac{\left(\frac{n}{r}\right)^r}{\binom{n}{r}} = \underbrace{\frac{\frac{n}{r}}{\frac{n}{r}} \cdot \frac{\frac{n}{r}}{\frac{n-1}{r-1}} \cdot \dots \cdot \frac{\frac{n}{r}}{\frac{n-r+1}{r-1}}}_{r} \le 1 \cdot 1 \cdot \dots \cdot 1 = 1$$

The second inequality follows immediately. To justify the last inequality, write

$$\left(\frac{en}{r}\right)^r = e^r \cdot \left(\frac{n}{r}\right)^r = \sum_{k=0}^{\infty} \frac{r^k}{k!} \cdot \left(\frac{n}{r}\right)^r$$

$$\geq \sum_{k=0}^r \frac{r^k}{k!} \cdot \left(\frac{n}{r}\right)^r$$

$$= \sum_{k=0}^r \frac{n^k \cdot n^{r-k}}{k! \cdot r^{r-k}}$$

$$\geq \sum_{k=0}^r \frac{n^k}{k!}$$

$$\geq \sum_{k=0}^r \binom{n}{r}$$
(Maclaurin series for e^x)
$$(by $n \geq r)$$$

Exercise 0.0.6 (Improved covering). Show that in the setting of Corollary 0.0.4, for $k \geq \lceil 1/\varepsilon^2 \rceil$

$$(C + C\varepsilon^2 m)^k$$

balls suffice for a suitable constant C.

Answer. We can give a tighter bound than given in the proof of Corollary 0.0.4 on the number of ball centres obtained from selecting a set of k points out of m with repetition (since computing the mean of k is order-invariant with respect to input points). By the "stars-and-bars" argument, this quantity is given by

$$\binom{m+k-1}{k-1}$$

Note that $\min\{k-1, m\} = k-1 \le \min\{k, m-1\}$, so looking at row m+k-1 of Pascal's triangle

$$\binom{m+k-1}{k-1} \le \binom{m+k-1}{k}$$

Then, using Exercise 0.0.5

$$\binom{m+k-1}{k} \leq \left(\frac{e(m+k-1)}{k}\right)^k = \left(e\frac{k-1}{k} + e\frac{1}{k}m\right)^k \leq (e + e\varepsilon^2 m)^k$$

†https://en.wikipedia.org/wiki/Stars_and_bars_(combinatorics)

1 Preliminaries on random variables

1.1 Basic quantities

The **expection** of a random variable X is denoted as $\mathbb{E}X$, and **variance** is denoted as $Var(X) = \mathbb{E}(X - \mathbb{E}X)^2$. (We note that the expectation operator \mathbb{E} can be directly defined as the Lebesgue integral of the random variable (measurable function) $X : \Omega \to \mathbb{R}$ in the probability space $(\Omega, \mathcal{M}, \mathbb{P})$.

The moment generating function of X is given by

$$M_X(t) = \mathbb{E}e^{tX}$$
 for all $t \in \mathbb{R}$

The **p-th moment** of X is given by $\mathbb{E}X^p$. We also let $||X||_p = (\mathbb{E}X^p)^{\frac{1}{p}}$ denote the **p-norm** of X. For $p = \infty$, we have

$$||X||_{\infty} = \operatorname{ess\,sup} X$$

recalling that the **essential supremum** of a function f is the "smallest value γ such that $\{\omega \in \Omega : |f(\omega)| > \gamma\}$ has measure 0".

From this, we can define the L^p spaces[‡], given a probability space $(\Omega, \mathcal{M}, \mathbb{P})$

$$L^p = \{X : ||X||_p < \infty\}$$

Results from measure and integration theory tell us that the $(L^p, \|\cdot\|_p)$ are complete. In the case of L^2 , we have that with the inner product

$$\langle X, Y \rangle = \int_{\Omega} XY(\omega)\mu(\omega)$$

= $\mathbb{E}XY$

 $(L^2, \langle \cdot, \cdot \rangle)$ is a Hilbert space. In this case we can express the **standard deviation** of X as $\sqrt{\text{Var}(X)} = \|X - \mathbb{E}X\|_2$, and the **covariance** of random variable X and Y as

$$Cov(X, Y) = \mathbb{E}(X - \mathbb{E}X)(Y - \mathbb{E}Y) = \langle X - \mathbb{E}X, Y - \mathbb{E}Y \rangle$$

In this setting, considering random variables as vectors in L^2 , the covariance between X and Y can be interpreted as the alignment between the vectors $X - \mathbb{E}X$ and $Y - \mathbb{E}Y$.

1.2 Some classical inequalities

We say $f: \mathbb{R} \to \mathbb{R}$ is **convex** if

$$f((1-t)x + ty) \le (1-t)f(x) + tf(y) \qquad \text{for all } x, y \in \mathbb{R} \text{ and } t \in [0, 1]$$

Jensen's inequality states that for any random variable X and a convex function f, we get

$$f(\mathbb{E}X) \le \mathbb{E}(f(X))$$

A corollary of Jensen's inequality implies that §

$$||X||_p \le ||X||_q$$
 for all $1 \le p \le q \le \infty$

Minkowski's inequality asserts that the triangle inequality holds for the L_p spaces

$$||X + Y||_p \le ||X||_p + ||Y||_p$$
 for all $X, Y \in L^p$

In L^2 , we have the Cauchy-Schwarz inequality, which states that $|\mathbb{E}XY| \leq \mathbb{E}|XY| \leq ||X||_2 ||Y||_2$. Holder's inequality additionally asserts that for 1/p + 1/q = 1

$$|\mathbb{E}XY| \le ||XY||_1 \le ||X||_p ||Y||_q$$

[†]A technical note is that the objects of L_p are actually equivalence classes of functions [X] with equality almost everywhere, otherwise $\|\cdot\|_p$ is only a semi-norm.

[§] For $q < \infty$, the result follows by applying Jensen's inequality for $f(x) = x^{\frac{q}{p}}$. Otherwise, $||X||_{\infty} = \gamma = (\mathbb{E}\gamma^p)^{\frac{1}{p}} = ||\gamma||_p \ge ||X||_p$.

which also holds for $p = 1, q = \infty$.

The cumulative distribution function of X is defined as

$$F_X(t) = \mathbb{P}\{X \le t\} = \mathbb{P}(X^{-1}(-\infty, t])$$
 for all $t \in \mathbb{R}$

and we refer to $\mathbb{P}\{X > t\} = 1 - F_X(t)$ as the **tail** of X.

Lemma 1.2.1 (Integral identity). Let $X \geq 0$ be a random variable. Then

$$\mathbb{E}X = \int_0^\infty \mathbb{P}\{X > t\}dt$$

with left side $= \infty$ iff right side $= \infty$.

Exercise 1.2.2 (Generalization of integral identity). Show that Lemma can be extended to be valid for any X

$$\mathbb{E}X = \int_0^\infty \mathbb{P}\{X > t\}dt - \int_{-\infty}^0 \mathbb{P}\{X < t\}dt$$

Answer. For not necessary non-negative X, $\mathbb{E}X := \mathbb{E}X^+ - \mathbb{E}X^-$ when they exist and are both $< \infty$, where

$$X^{+} = \begin{cases} X & \text{if } X \ge 0\\ 0 & \text{otherwise} \end{cases} \qquad X^{-} = \begin{cases} -X & \text{if } X \le 0\\ 0 & \text{otherwise} \end{cases}$$

Applying Lemma 1.2.1 to the terms yields the result. For the second term

$$\mathbb{E} X^{-} = \int_{0}^{\infty} \mathbb{P}\{X^{-} > t\} dt = \int_{0}^{\infty} \mathbb{P}\{X < -t\} dt = \int_{-\infty}^{0} \mathbb{P}\{X < t\} dt$$

Exercise 1.2.3 (p-th moment via the tail). Let X be a random variable and 0 . Show that

$$\mathbb{E}|X|^p = \int_0^\infty pt^{p-1} \mathbb{P}\{|X| > t\} dt$$

whenever the right side is $< \infty$.

Answer. On the right side, substitute $u = t^p$, so $du = pt^{p-1}dt$ and

$$\int_0^\infty p t^{p-1} \mathbb{P}\{|X| > t\} dt = \int_0^\infty \mathbb{P}\{|X| > u^{\frac{1}{p}}\} du = \int_0^\infty \mathbb{P}\{|X|^p > u\} du = \mathbb{E}|X|^p$$

where the last equality comes from applying Lemma 1.2.1 to the random variable $|X|^p \ge 0$.

Proposition 1.2.4 (Markov's inequality). Let $X \geq 0$ with $\mathbb{E}X < \infty$. Then for t > 0

$$\mathbb{P}\{X \ge t\} \le \frac{\mathbb{E}X}{t}$$

Proof. Fix t > 0. Applying Lemma 1.2.1

$$\mathbb{E}X = \int_0^\infty \mathbb{P}\{X \ge x\} dx \ge \int_0^t \mathbb{P}\{X \ge x\} dx \ge \int_0^t \mathbb{P}\{X \ge t\} dx = t \cdot \mathbb{P}\{X \ge t\}$$

Corollary 1.2.5 (Chebyshev's inequality). Let X have $\mathbb{E}X < \infty$ and $\mathrm{Var}(X) < \infty$. Then for t > 0

$$\mathbb{P}\{|X - \mathbb{E}X| > t\} \le \frac{\operatorname{Var}(X)}{t^2}$$

Exercise 1.2.6. Give a proof of Chebyshev's inequality using Markov's inequality.

Answer. The random variable $|X - \mathbb{E}X|^2$ is well-defined (by $\mathbb{E}X < \infty$), non-negative, with finite expectation. Applying Markov's inequality with $t^2 > 0$ yields

$$\mathbb{P}\{|X - \mathbb{E}X| \ge t\} = \mathbb{P}\{|X - \mathbb{E}X|^2 \ge t^2\} \le \frac{\operatorname{Var}(X)}{t^2}$$

1.3 Limits theorems

For independent and identically distributed variables $X_1, ..., X_N$, the sample mean $\frac{1}{N} \sum_{i=1}^N X_i$ has

$$\operatorname{Var}(\frac{1}{N}\sum_{i=1}^{N}X_i) = \frac{\operatorname{Var}(X_1)}{N} \to 0 \text{ as } N \to \infty$$

so we should expect it to concentrate around the true mean.

Theorem 1.3.1 (Strong law of large numbers). Let $X_1, X_2, ...$ be a sequence of i.i.d. random variables with $\mathbb{E}X_1 < \infty$. Then the averaged partial sums

$$\frac{S_N}{N} = \frac{1}{N} \sum_{i=1}^N X_i \to \mathbb{E} X_1$$
 almost surely

where random variables $(Y_N)_{N=1}^{\infty}$ are said to **converge almost surely** to a random variable Y if there exists measurable $Z \in \mathcal{M}$ with $\mathbb{P}(Z) = 0$ and

$$\lim_{N \to \infty} Y_N(\omega) = Y(\omega) \quad \text{for every } \omega \in \Omega \setminus Z$$

Theorem 1.3.2 (Lindeberg-Lévy CLT). Let $X_1, X_2, ...$ be a sequence of i.i.d. random variables with $\mathbb{E}X_1 = \mu$, $\operatorname{Var}(X_1) = \sigma^2 < \infty$. Then the normalized partial sums

$$Z_N = \frac{S_N - \mathbb{E}S_N}{\sqrt{\operatorname{Var}(S_N)}} = \frac{\sum_{i=1}^N X_i - N\mu}{\sigma\sqrt{N}} \to N(0,1)$$
 in distribution

where real random variables $(Y_N)_{N=1}^{\infty}$ are said to **converge in distribution** to a random variable Y if their CDF's $F_{Y_N}(t) := \mathbb{P}\{Y_N \leq t\}$, $F_Y(t) := \mathbb{P}\{Y \leq t\}$ have

$$\lim_{N \to \infty} F_{Y_N}(t) = F_Y(t) \quad \text{for all } t \in \mathbb{R}$$

Exercise 1.3.3. Let $X_1, X_2, ...$ be a sequence of i.i.d. random variables with $\mu, \sigma^2 < \infty$. Show that

$$\mathbb{E}\left|\frac{1}{N}\sum_{i=1}^{N}X_{i}-\mu\right|=O(\frac{1}{\sqrt{N}})$$

Answer. Considering the convex function $\phi(x) = x^2$, we can apply Jensen's to get

$$\left(\mathbb{E}\left|\frac{1}{N}\sum_{i=1}^{N}X_{i}-\mu\right|\right)^{2} \leq \operatorname{Var}\left(\frac{1}{N}\sum_{i=1}^{N}X_{i}\right) = \frac{\sigma^{2}}{N}$$

taking the square root of both sides yields the result.

Theorem 1.3.4 (Poisson limit theorem). Consider a sequence of N-tuples of independent random variables with entries X_{Ni} for $1 \le i \le N$ with $X_{Ni} \sim \text{Bernoulli}(p_{Ni})$. Let $S_N = \sum_{i=1}^N X_{Ni}$, and suppose that as $N \to \infty$

$$\max_{1 \le i \le N} p_{Ni} \to 0 \quad \text{and} \quad \mathbb{E}S_N = \sum_{i=1}^N p_{Ni} \to \lambda$$

Then $S_N \to \operatorname{Poisson}(\lambda)$ in distribution, i.e. the CDF $F_{S_N}(t) = \mathbb{P}\{S_N \leq t\}$ has

$$\lim_{N \to \infty} F_{S_N}(t) = \sum_{k=1}^{\lfloor t \rfloor} e^{-\lambda} \frac{\lambda^k}{k!}$$

2 Concentrations of sums of independent random variables

2.1 Why concentration inequalities?

Concentration inequalities quantify the variation of a random variable around its mean, and take the from

$$\mathbb{P}\{|X - \mu| \ge t\} \le \text{ something small }$$

Proposition 2.1.2 (Tails of the normal distribution). Let $Z \sim N(0,1)$. For t > 0

$$\left(\frac{1}{t} - \frac{1}{t^3}\right) \frac{1}{\sqrt{2\pi}} e^{-t^2/2} \le \mathbb{P}\{Z \ge t\} \le \frac{1}{t} \frac{1}{\sqrt{2\pi}} e^{-t^2/2}$$

In particular, for $t \geq 1$, the tail of Z has

$$\mathbb{P}\{Z \ge t\} \le \frac{1}{\sqrt{2\pi}}e^{-t^2/2}$$

More loosely, we can say

$$\mathbb{P}\{Z \geq T\} = \Theta\left(\frac{1}{te^{t^2/2}}\right) = \tilde{\Theta}\left(\frac{1}{e^{t^2/2}}\right)$$

Proof. For the upper bound, we substitute x = y + t to get

$$\int_{t}^{\infty} \frac{1}{\sqrt{2\pi}} e^{-x^{2}/2} dx = \int_{0}^{\infty} \frac{1}{\sqrt{2\pi}} e^{-y^{2}/2} e^{-ty} e^{-t^{2}/2} dy \leq \frac{1}{\sqrt{2\pi}} e^{-t^{2}/2} \int_{0}^{\infty} e^{-ty} dy = \frac{1}{t} \frac{1}{\sqrt{2\pi}} e^{-t^{2}/2} dy = \frac{1}{t} \frac{1}{t} \frac{1}{\sqrt{2\pi}} e^{-t^{2}/2} dy = \frac{1}{t} \frac$$

For the lower bound, we make use of the identity

$$\int_{t}^{\infty} e^{-x^{2}/2} dx \ge \int_{t}^{\infty} (1 - 3x^{-4}) e^{-x^{2}/2} dx = \left(\frac{1}{t} - \frac{1}{t^{3}}\right) e^{-t^{2}/2}$$

Example 2.1.1. Consider $S_N = X_1 + ... + X_N$, each $X_i \sim \text{Bernoulli}(1/2)$. We have $\mathbb{E}S_N = N/2, \text{Var}(S_N) = N/4$. From Chebyshev's inequality (Corollary 1.2.5), we get

$$\mathbb{P}\left\{ \left| S_N - \frac{N}{2} \right| \ge \frac{N}{4} \right\} \le \frac{4}{N} = O\left(\frac{1}{N}\right)$$

i.e. the probability of satisfying our concentration requirements goes to 0 linearly. Is this upper bound tight?

We know by the CLT (Theorem 1.3.2), that our normalized S_N converges in distribution to N(0,1). Then for large N, we should see that

$$\mathbb{P}\left\{\left|S_N - \frac{N}{2}\right| \ge \frac{N}{4}\right\} = \mathbb{P}\left\{\left|\frac{S_N - \frac{N}{2}}{\sqrt{\frac{N}{4}}}\right| \ge \sqrt{\frac{N}{4}}\right\} \approx \mathbb{P}\left\{|Z| \ge \sqrt{\frac{N}{4}}\right\} \le \frac{1}{\sqrt{2\pi N}}e^{-N/8} = \tilde{O}\left(\frac{1}{e^{N/8}}\right)$$

which is exponentially fast (by Proposition 2.1.2). However this central limit theorem argument can't be made rigourous, since the error in approximating normalized S_N with Z decays too slowly (in fact slower than linearly via Theorem 2.1.3). It turns out that for these sums, we get light tails much faster than we approximate N(0,1).

Theorem 2.1.3 (Berry-Esseen CLT). In the setting of Theorem 1.3.2, for all N

$$|F_{Z_N}(t) - F_Z(t)| \le \frac{\rho}{\sqrt{N}}$$
 for all $t \in \mathbb{R}$

where $\rho = \mathbb{E}|X_1 - \mu|^3/\sigma^3$.

Note that in comparison to Theorem 1.3.2 it additionally requires the third moment $\mathbb{E}X_1^3 < \infty$, and in turn provides a quantitative rate for uniform convergence in distribution to N(0,1).

Exercise 2.1.4 (Truncated normal distribution). Let $Z \sim N(0,1)$. Show that for all t > 0

$$\mathbb{E}Z^2 \mathbb{1}_{\{Z \ge t\}} = t \frac{1}{\sqrt{2\pi}} e^{-t^2/2} + \mathbb{P}(Z \ge t) \le \left(t + \frac{1}{t}\right) \frac{1}{\sqrt{2\pi}} e^{-t^2/2}$$

Answer. To prove the equality

$$\mathbb{E} Z^2 \mathbb{1}_{\{Z \geq t\}} := \int_t^\infty z^2 \frac{1}{\sqrt{2\pi}} e^{-z^2/2} dz = \frac{1}{\sqrt{2\pi}} \left(\left[-z e^{-z^2/2} \right]_t^\infty + \int_t^\infty e^{-z^2/2} dz \right) = t \frac{1}{\sqrt{2\pi}} e^{-t^2/2} + \mathbb{P}\{Z \geq t\}$$

The inequality follows from the tail upper bound from Proposition 2.1.2.

2.2 Hoeffding's inequality

Definition 2.2.1 (Rademacher distribution). We say a random variable X has **Rademacher** distribution if

$$\mathbb{P}\{X = -1\} = \mathbb{P}\{X = 1\} = \frac{1}{2}$$

Theorem 2.2.2 (Hoeffding's inequality). Let $X_1, ..., X_N$ be independent Rademacher random variables. Let $a = (a_1, ..., a_n) \in \mathbb{R}^N$. For $t \geq 0$

$$\mathbb{P}\left\{\sum_{i=1}^{N} a_i X_i \ge t\right\} \le \exp\left(\frac{-t^2}{2\|a\|_2^2}\right)$$

Proof. WLOG assume $||a||_2^2 = 1$. If we prove this version of the theorem, then for any $b = ca \in \mathbb{R}^N$,

$$\mathbb{P}\left\{\sum_{i=1}^{N}b_{i}X_{i} \geq t\right\} = \mathbb{P}\left\{\sum_{i=1}^{N}a_{i}X_{i} \geq t/c\right\} \leq \exp\left(\frac{-t^{2}}{2c^{2}\|a\|_{2}^{2}}\right) = \exp\left(\frac{-t^{2}}{2\|b\|_{2}^{2}}\right)$$

We apply Markov's inequality to the MGF of $\sum_{i=1}^{N} a_i X_i$

$$\mathbb{P}\left\{\sum_{i=1}^{N} a_i X_i \ge t\right\} = \mathbb{P}\left\{\exp\left(\lambda \sum_{i=1}^{N} a_i X_i\right) \ge \exp\left(\lambda t\right)\right\} \le \frac{\mathbb{E}\exp\left(\lambda \sum_{i=1}^{N} a_i X_i\right)}{\exp(\lambda t)}$$

Examining the numerator of the right side of the inequality

$$\mathbb{E} \exp\left(\lambda \sum_{i=1}^{N} a_i X_i\right) = \prod_{i=1}^{N} \mathbb{E} \exp(\lambda a_i X_i)$$
 (by independence of X_i)
$$= \prod_{i=1}^{N} \cosh(\lambda a_i)$$
 (by definition of \mathbb{E} of Rademacher RVs)
$$\leq \prod_{i=1}^{N} \exp(\lambda^2 a_i^2/2)$$
 (by Exercise 2.2.3)
$$= \exp(\lambda^2/2)$$
 (since $||a||_2^2 = 1$)

To complete the proof we optimize λ to minimize the right hand side of the expression

$$\exp(\lambda^2/2 - \lambda t)$$

Setting $d(\lambda^2/2 - \lambda t)/d\lambda = \lambda - t = 0$ yields the minimum $\lambda = t$. This yields the desired inequality

$$\mathbb{P}\left\{\sum_{i=1}^{N} a_i X_i \ge t\right\} \le \exp(-t^2/2||a||_2^2)$$

Exercise 2.2.3 (Bounding the hyperbolic cosine). Show that

$$\cosh(x) \le \exp(x^2/2)$$
 for all $x \in \mathbb{R}$

2.3 Chernoffs's inequality
